

## Data Structures

### Chapter 4

1. Singly Linked List
2. Doubly Linked List
  - **Revisit – Singly Linked List**
  - **Sentinel Nodes & Basic Operations**
  - Two Key Operations: erase, insert
  - Advanced Operations

A pair of black-rimmed glasses is placed on an open book. The book's pages are yellowed with age, and the text is faint and illegible. The background is a warm, golden-brown color.

우리가 알거니와 하나님을 사랑하는 자 곧 그의 뜻대로 부르심을 입은 자들에겐 모든 것이  
협력하여 선을 이루느니라 (롬8:28)

And we know that in all things God works for the good of those who love him, who  
have been called according to his purpose. (Rom8:28)

하나님이 우리를 구원하사 거룩하신 소명으로 부르심은 우리의 행위대로 하심이 아니요 오직  
자기의 뜻과 영원 전부터 그리스도 예수 안에서 우리에게 주신 은혜대로 하심이라 (딤후1:9)

# Linked List – reverse using stack

With an error

Algorithm:  
Step 1. Push all nodes onto the stack.  
**Step 2. Top/pop all nodes and relink.**

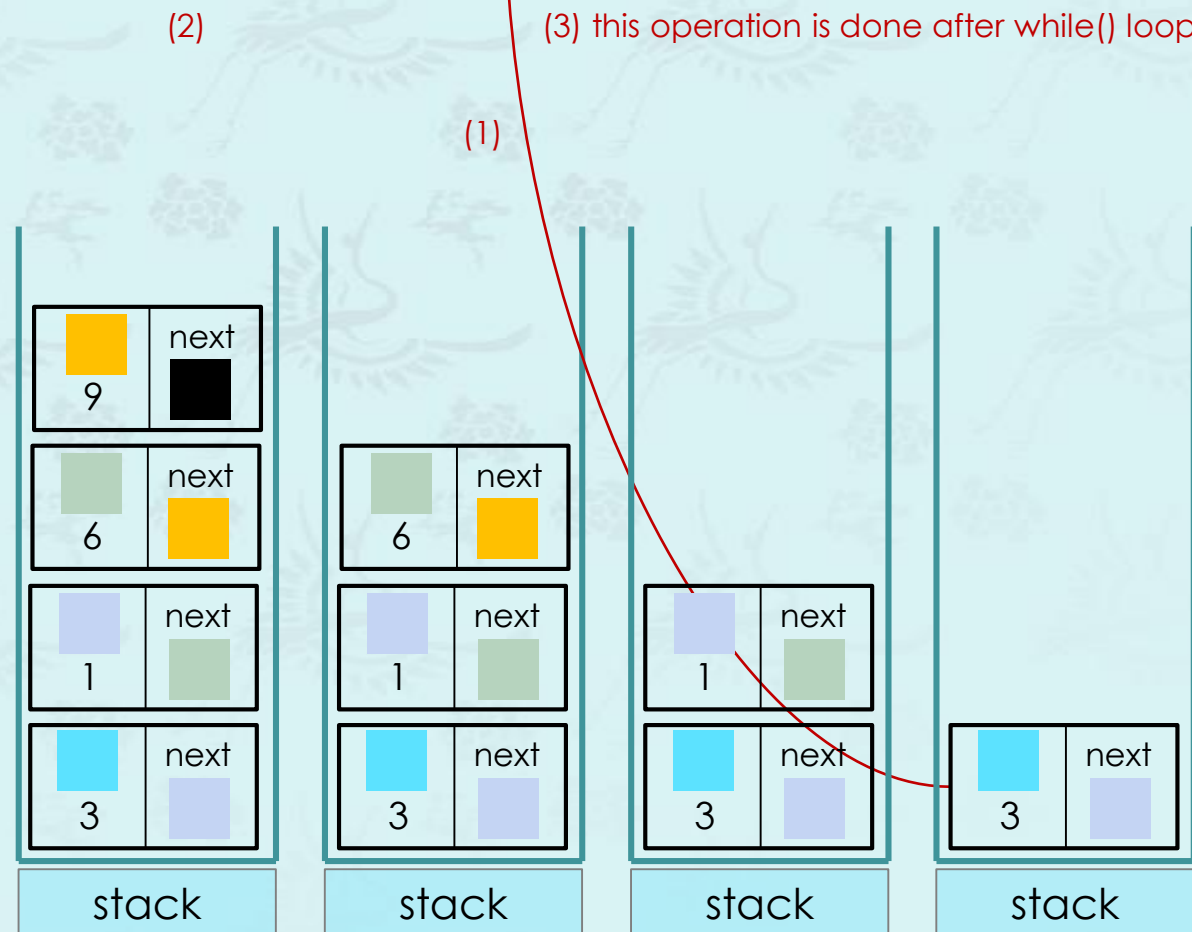

## Linked List – reverse using stack

Corrected:

Algorithm:  
Step 1. Push all nodes onto the stack.  
**Step 2. Top/pop all nodes and relink.**

# A Node and List Data Structure with Constructor and Destructor

```
struct Node {  
    int    data;  
    Node*  prev; ← unused in  
    Node*  next;   singly linked  
};  
  
struct List {  
    Node*  head;  
    Node*  tail;  
    int    size; //optional  
};  
using pNode = Node*;  
using pList = List*;
```

```
struct Node {  
    int    data;  
    Node*  prev;  
    Node*  next;  
    Node(int d = 0, Node* p = nullptr,  
           Node* x = nullptr)  
        { data = d; prev = p; next = x; }  
    ~Node() {}  
};  
  
struct List {  
    Node*  head;  
    Node*  tail;  
    int    size; // optional  
    List() { head = new Node{}; tail = new Node{};  
            head->next = tail; tail->prev = head;  
            size = 0;  
    }  
    ~List() {}  
};  
  
using pNode = Node*;  
using pList = List*;
```

## push a node – three different cases

Given: an data(4) **to insert as sorted** – What was the most difficult part of this coding?

Case 1: in front

Case 2: in middle

Case 3: at end

## push a node – **Case 1**: insert in front, head given

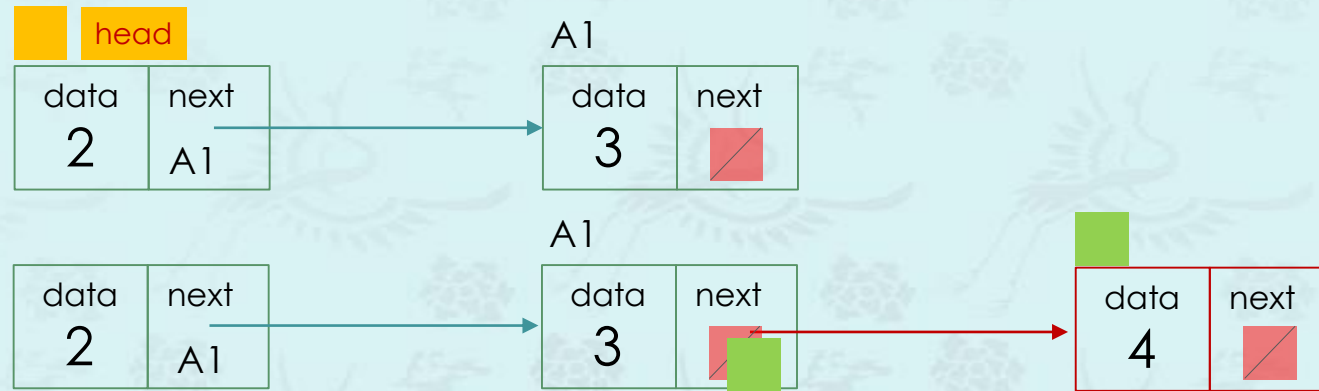

```
void push_front(pList p, int value) {  
    p->head = new Node{value, p->head};  
}
```

```
struct Node{  
    int data;  
    Node* next;  
    Node(const int d = 0, pNode x = nullptr){  
        data = d;        next = x;  
    }  
    ~Node() {}  
};
```

```
struct List {  
    Node* head;  
    Node* tail;  
    int size; //optional  
};  
using pList = List*;
```

## push a node – **Case 3**; insert at end, head given

Append a new Node{4}; then find the last node first to append.

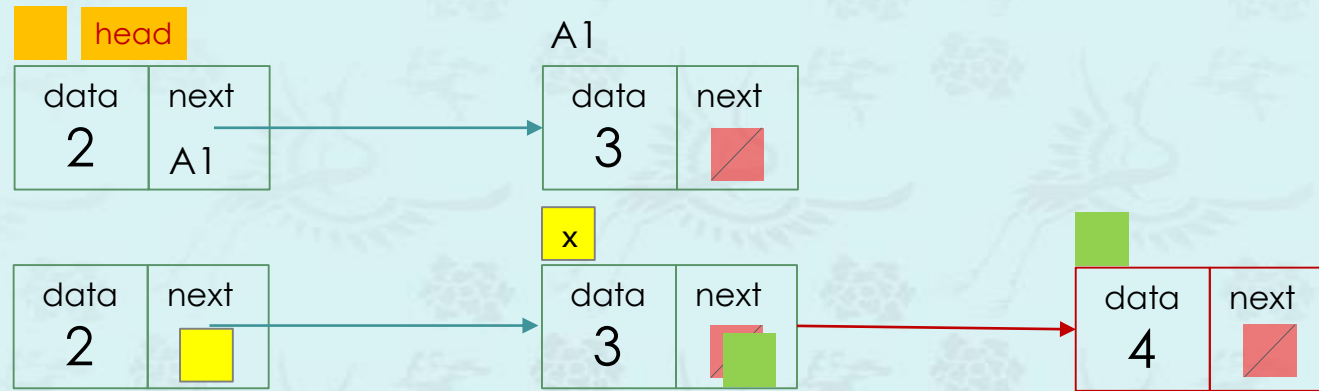

```
void push_back(pList p, int value) {  
      
}  

```

## push a node – **Case 3**; insert at end, head given

Append a new Node{4}; then find the last node first to append.

$O(n)$

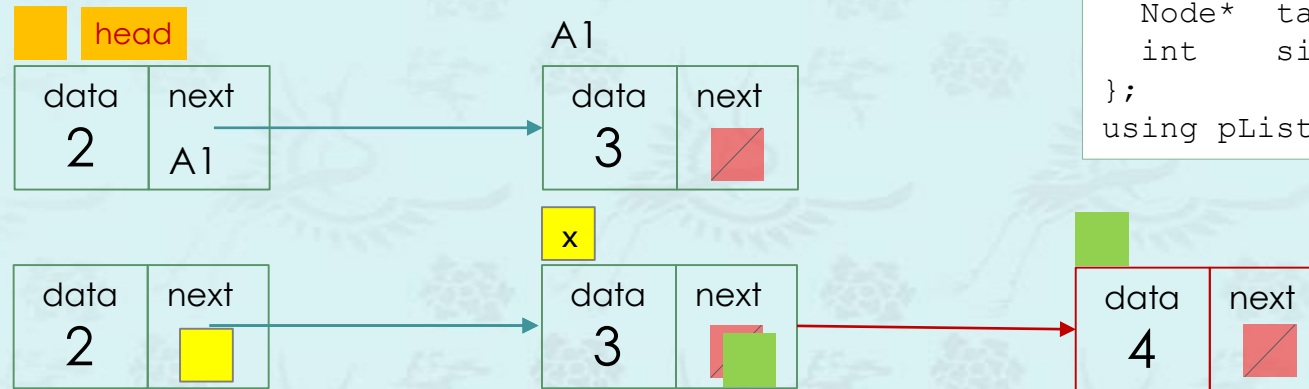

```
void push_back(pList p, int value) {  
    pNode x = last(p->head);  
    x->next = new Node{ value, nullptr };  
}
```

```
pNode last(pNode head)
```

```
while (head->next != nullptr)  
    head = head->next;  
return head;
```

## push a node – **Case 3**; insert at end, head given

```
struct List {
    Node* head;
    Node* tail;
    int size; //optional
};
using pList = List*;
```

$O(n)$

```
void push_back(pList p, int value) {
    pNode x = last(p->head);
    x->next = new Node{ value, nullptr };
}
```

pNode last(pNode head)

```
while (head->next != nullptr)
    head = head->next;
return head;
```

$O(1)$

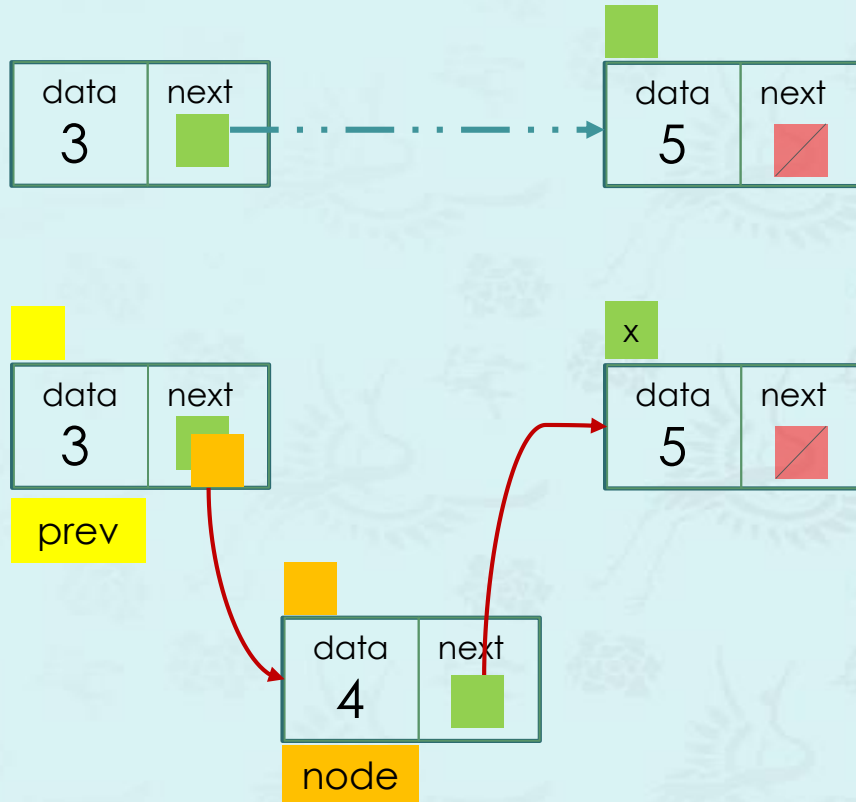

```
void push_back(pList p, int value) {
    p->tail->next = new Node{ val };
    p->tail = p->tail->next;
}
```

```
void push_back(pList p, int value) {
    p->tail = p->tail->next = new Node{ val };
}
```

it can be shortened

## push a node – **Case 2**; insert in middle, head given

```
// inserts a node val at node z
void push_at(pList p, int value, int z) {
    if (empty(p) || (p->head->data == z) )
        return push_front(p, value);
```

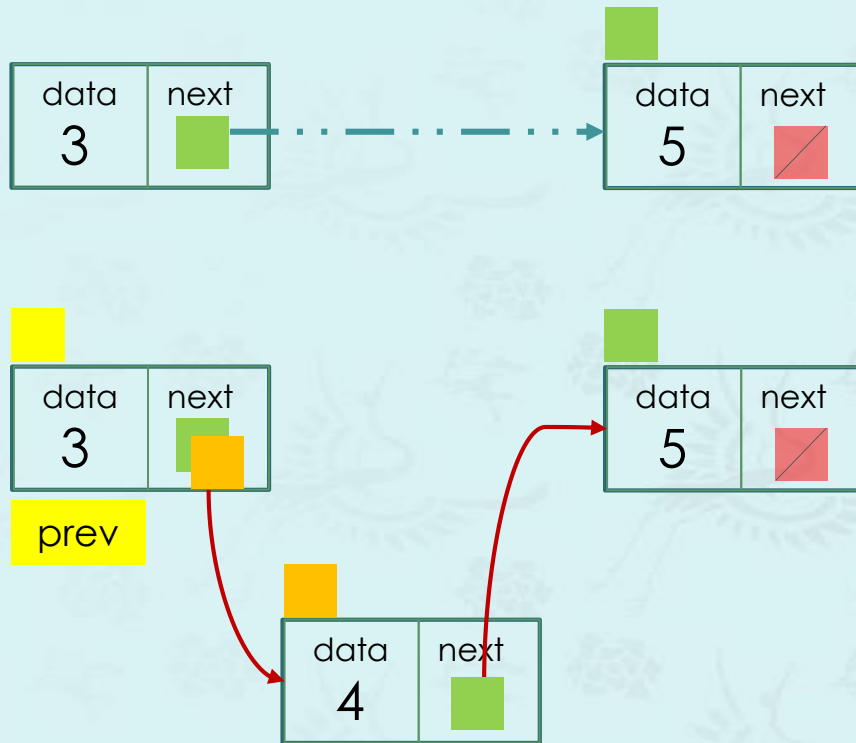

```
pNode x = p->head;
pNode prev = nullptr;
while (x != nullptr) {
```

```
    prev = x;
    x = x->next;
```

```
}
```

```
}
```

## push a node – **Case 2**; insert in middle, head given

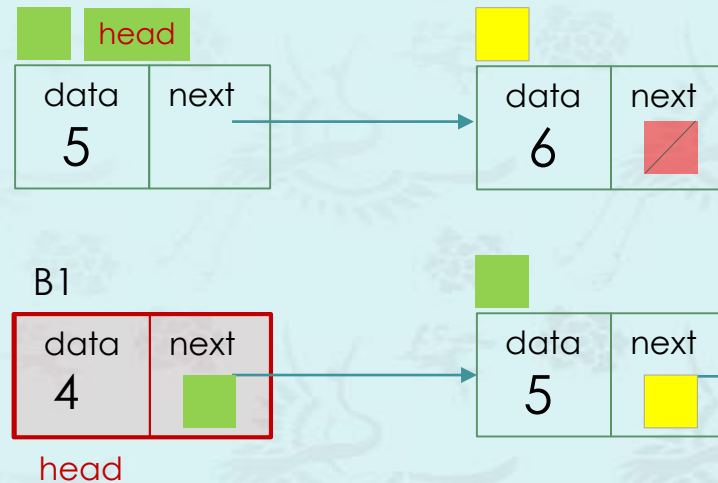

```
// inserts a node val at node z
void push_at(pList p, int value, int z) {
    if (empty(p) || (p->head->data == z) )
        return push_front(p, value);

    pNode x = p->head;
    pNode prev = nullptr;
    while (x != nullptr) {
        if (x->data == z) {
            prev->next = new Node{value, prev->next};
            return;
        }
        prev = x;
        x = x->next;
    }
}
```

## push a node – Three different cases

Given: an data(4) to insert – **What was the most difficult part of this coding?**

Case 1: in front

Case 2: in middle

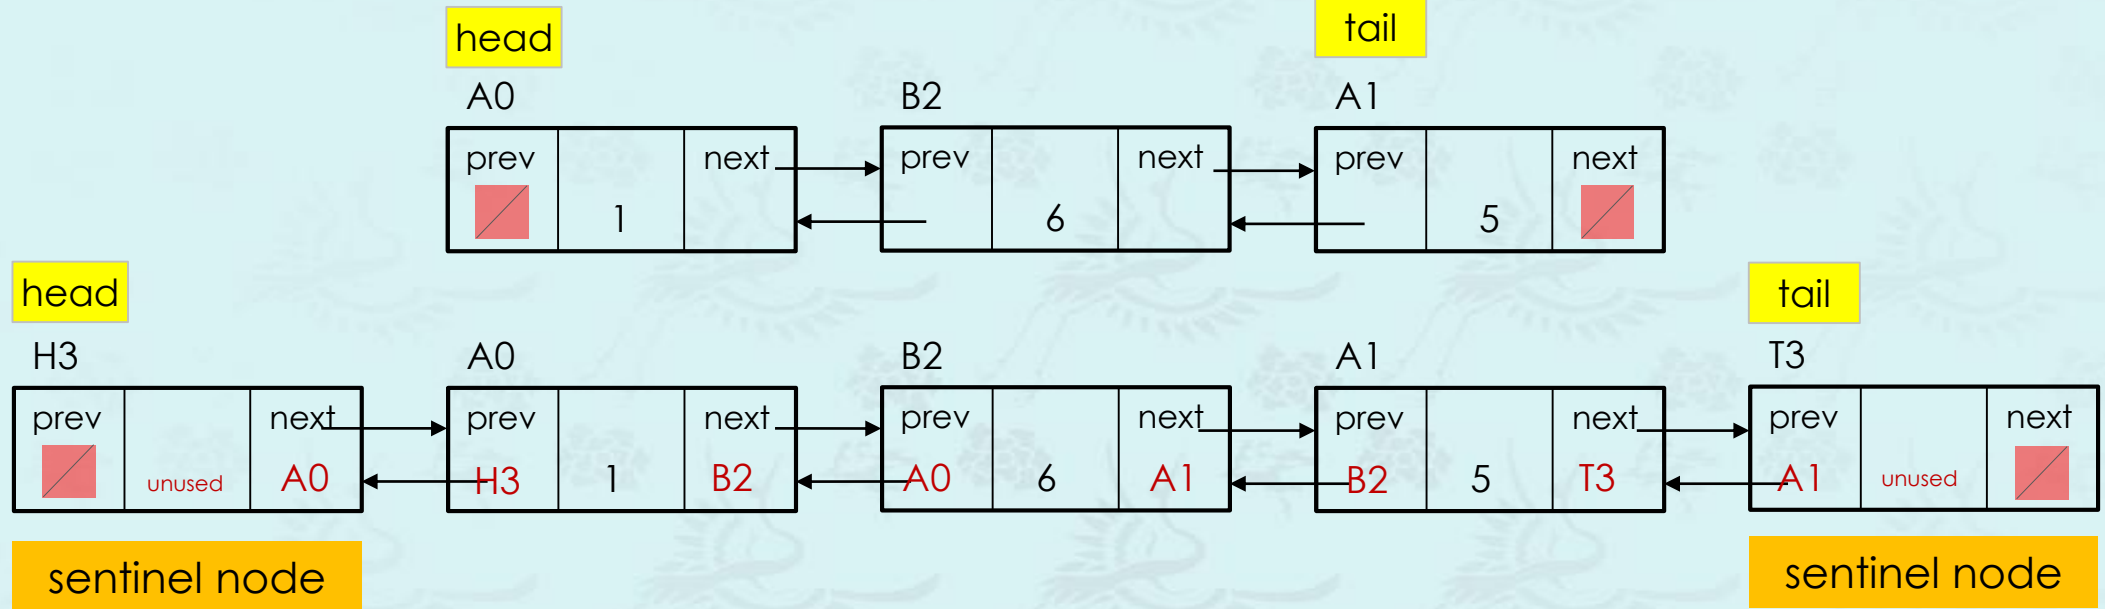

Case 3: at end

- Coding case by case
  - front, back, or middle
  - not generalized
- Lack of information about
  - the previous node
  - the tail/last node
- **Solution?**
  - have previous node information
  - have sentinel nodes

# doubly linked list with sentinel nodes

- **Solution**

- **doubly linked list with two sentinel nodes**
- Each node carries the pointer to the previous node.
- There is only one case (middle) with two sentinel nodes.

## doubly linked list with sentinel nodes

- These extra nodes are known as **sentinel nodes**. The node at the front is known as **head node**, and the node at the end as a **tail node**. The head and tail nodes are created when the doubly linked list is initialized. The purpose of these nodes is to simply the insert, push/pop front and back, remove methods by eliminating all need for special-case code when the list empty, or when we insert at the head or tail of the list. **This would greatly simplify the coding unbelievably.**
- For instance, if we do not use a head node, then removing the first node becomes a special case, because we must reset the list's link to **the first node** during the remove and because the remove algorithm in general needs to access the node prior to the node being removed (and without a head node, the first node does not have a node prior to it).

# doubly linked list with sentinel nodes

    }
    ~List() {}
};
```

```
using pNode = Node*;
using pList = List*;
```

An **empty** doubly-linked list with sentinel nodes

# Basic Operations:

```
pNode begin(pList p) {  
    return p->head->next;  
}
```

← What is the name of this function?

```
pNode end(pList p) {  
    return p->tail;  
}
```

← What is the name of this function?

## Basic Operations: begin() and end()

```
// returns the first node which list::head points to in the container.  
pNode begin(pList p) {  
    return p->head->next;  
}
```

```
// returns the tail node referring to the past -the last- node in the list.  
// The past -the last- node is the sentinel node which is used only as a sentinel that would  
// follow the last node. It does not point to any node next, and thus shall not be dereferenced.  
// Because the way we are going use during the iteration, we don't want to include the node  
// pointed by this. This function is often used in combination with List::begin to specify a  
// range including all the nodes in the list. This is a kind of simulated used in STL. If the  
// container is empty, this function returns the same as List::begin.
```

```
pNode end(pList p) {  
    return p->tail;  
}
```

With the container given below,  
what does begin(p) and end(p) return  
in mnemonic code, respectively?

# Basic Operations:

```
pNode begin(pList p) {  
    return p->head->next;  
}
```

← What is the return value of begin() in mnemonic shown above?

```
pNode end(pList p) {  
    return p->tail;  
}
```

← What is the return value of begin() in mnemonic shown above?

# Basic Operations:

```
pNode begin(pList p) {  
    return p->head->next;  
}
```

```
bool empty(pList p) {  
    return begin(p) == end(p);  
}
```

```
pNode end(pList p) {  
    return p->tail;  
}
```

```
pNode last(pList p) {  
    return end(p)->prev;  
}
```

An **empty** doubly-linked list with sentinel nodes

# Basic Operations:

```
int size(pList p) {  
    int count = 0;  
      
    return count;  
}
```

```
int size(pList p) {  
    int count = 0;  
    pNode x = begin(p);  
    while(x != end(p)) {  
        count++;  
        x = x->next;  
    }  
    return count;  
}
```

# Basic Operations:

```
int size(pList p) {  
    int count = 0;  
    for (pNode x = begin(p); x != end(p); x = x->next)  
        count++;  
    return count;  
}
```

```
int size(pList p) {  
    int count = 0;  
    pNode x = begin(p);  
    while(x != end(p)) {  
        count++;  
        x = x->next;  
    }  
    return count;  
}
```

# Basic Operations:

```
int find(pList p, int value) {
    for (pNode x = begin(p); x != end(p); x = x->next)
        if (x->data == value) return x;
    return x;
} // there is a bug.
```

```
int find(pList p, int value) {
    pNode x = begin(p);
    for ( ; x != end(p); x = x->next)
        if (x->data == value) return x;
    return x;
}
```

```
pNode find(pList p, int value){
    pNode x = begin(p);
    while(x != end(p)) {
        if (x->data == value) return x;
        x = x->next;
    }
    return x;
}
```

# Basic Operations:

- What does it return if not found? →  
(1) A1, (2) tail, (3) nullptr.

```
pNode find(pList p, int value){  
    pNode x = begin(p);  
    while(x != end(p)) {  
        if (x->data == value) return x;  
        x = x->next;  
    }  
    return x;  
}
```

# Basic Operations:

```
pNode find(pList p, int value){  
    pNode x = begin(p);  
      
    return x;  
}
```

```
pNode find(pList p, int value){  
    pNode x = begin(p);  
    while(x != end(p)) {  
        if (x->data == value) return x;  
        x = x->next;  
    }  
    return x;  
}
```
